PRIORITY DOCUMENT

SUBMITTED OR TRANSMITTED IN
 COMPLIANCE WITH RULE 17.1(a) OR (b)

REC'D 14 JUN 2004

WIPO

PCT

I, the undersigned, being an officer duly authorised in accordance with Section 74(1) and (4) of the Deregulation & Contracting Out Act 1994, to sign and issue certificates on behalf of the Comptroller-General, hereby certify that annexed hereto is a true copy of the documents as originally filed in connection with the patent application identified therein.

In accordance with the Patents (Companies Re-registration) Rules 1982, if a company named in this certificate and any accompanying documents has re-registered under the Companies Act 1980 with the same name as that with which it was registered immediately before re-registration save for the substitution as, or inclusion as, the last part of the name of the words "public limited company" or their equivalents in Welsh, references to the name of the company in this certificate and any accompanying documents shall be treated as references to the name with which it is so re-registered.

In accordance with the rules, the words "public limited company" may be replaced by p.l.c., plc, P.L.C. or PLC.

Re-registration under the Companies Act does not constitute a new legal entity but merely subjects the company to certain additional company law rules.

Request for grant of a patent

(See the notes on the back of this form. You can also get an explanatory leaflet from the Patent Office to help you fill in this form)

1. Your reference

A30311

2. Patent application number
(The Patent Office will fill in this part)

0306294.0

19 MAR 2003

3. Full name, address and postcode of the or of each applicant (underline all surnames)

BRITISH TELECOMMUNICATIONS public limited company
81 NEWGATE STREET
LONDON, EC1A 7AJ, England
Registered in England: 1800000

Patents ADP number (if you know it)

1867002⁸

If the applicant is a corporate body, give the country/state of its incorporation

UNITED KINGDOM

4. Title of the invention

FLEXIBLE MULTI-AGENT SYSTEM ARCHITECTURE

5. Name of your agent (if you have one)

"Address for Service" in the United Kingdom to which all correspondence should be sent (including the postcode)

BT GROUP LEGAL
INTELLECTUAL PROPERTY DEPARTMENT
HOLBORN CENTRE
120 HOLBORN
LONDON, EC1N 2TE

Patents ADP number (if you know it)

1867001

85919 19001

6. If you are declaring priority from one or more earlier patent applications, give the country and the date of filing of the or of each of these earlier applications and (if you know it) the or each application number

Country

Priority application number
(if you know it)

Date of filing
(day / month / year)

7. If this application is divided or otherwise derived from an earlier UK application, give the number and the filing date of the earlier application

Number of earlier application

Date of filing
(day/month/year)

8. Is a statement of inventorship and of right to grant of a patent required in support of this request? (Answer 'Yes' if:

- a) any applicant named in part 3 is not an inventor, or
- b) there is an inventor who is not named as an applicant, or
- c) any named applicant is a corporate body.

YES

(See note (d))

9. Enter the number of sheets for any of the following items you are filing with this form.
☐ not count copies of the same document

Continuation sheets of this form

Warning

After an application for a patent has been filed, the Comptroller of the Patent Office will consider whether publication or communication of the invention should be prohibited or restricted under Section 22 of the Patents Act 1977. You will be informed if it is necessary to prohibit or restrict your invention in this way. Furthermore, if you live in the United Kingdom, Section 23 of the Patents Act 1977 stops you from applying for a patent abroad without first getting written permission from the Patent Office unless an application has been filed at least 6 weeks beforehand in the United Kingdom for a patent for the same invention and either no direction prohibiting publication or communication has been given, or any such direction has been revoked.

Notes

- If you need help to fill in this form or you have any questions, please contact the Patent Office on 0645 500505.
- Write your answers in capital letters using black ink or you may type them.
- If there is not enough space for all the relevant details on any part of this form, please continue on a separate sheet of paper and write "see continuation sheet" in the relevant part(s). Any continuation sheet should be attached to this form.
- If you have answered 'Yes' Patents Form 7/77 will need to be filed.
- Once you have filled in the form you must remember to sign and date it.
- For details of the fee and ways to pay please contact the Patent Office.

Flexible Multi-Agent System Architecture

The present invention relates to a multi-agent system (MAS) architecture, in particular to a multi-agent system architecture which is suitable for Open Electronic
5 Commerce. The invention further relates to a method and mediator agent for providing generic role components to other agents in the MAS.

Software agent technology is widely used in a variety of applications ranging from comparatively small systems such as personalised email filters to large, complex, and
10 mission-critical systems such as air-traffic control. Multi-Agent Systems (MASs) are designed and implemented using multiple software agents that interact via messages to achieve a goal:

In a MAS, each agent has incomplete information or a limited capability for solving a
15 problem. Therefore an agent must interact with other agents autonomously. A MAS can be differentiated from existing distributed object systems in that each agent autonomously detects and solves a problem using its reasoning facility minimizing the human user's intervention.

20 One of the main MAS principles concerns the separation of service provision and service requests amongst the distributed agents. If one agent cannot perform a task, it adopts the role of a client agent and requests assistance from another agent (acting in the role of server agent) which satisfies the request by executing the required service.

25

Currently, interactions among multiple agents are affected by certain limitations of known MASs. These limitations include interoperability issues among heterogeneous agents, the semantics of the agent communication language (ACL) used which specifies the standard agent message structures, the allocation of tasks among
30 participant agents, and the building of conversation policies (or interaction protocols) etc. (For more details see Mamadou T. Kone, Akira Shimazu and Tatsuo Nakajima, "The state of the art in agent communication languages", in Knowledge and Information Systems (2000) 2: 259-284; and Jennings, N. R., Sycara, K., and

Wooldridge, M., "A roadmap of agent research and development", Autonomous Agents and Multi-Agent Systems, 1, 275-306, 1998.

Interoperability is mainly concerned with making different agents communicate with each other by using standard ACL and interaction protocols etc. It involves several areas of research such as ontology, content language, and ACL. Ontologies provide common representations of knowledge for specific domains where agent communication is made. Content languages are standard expressions of domain-independent knowledge that are used together with ontologies to specify the content part of agent messages.

Whilst interoperability is not an issue when all agents on the same platform use a predefined language, ontology, and interaction protocols to compose an ACL, this situation is unrealistic in an electronic commerce environment where new agents are dynamically introduced with new services.

FIPA (The Foundation for Intelligent Physical Agents) aims to produce standards for the interoperation of heterogeneous software agents. FIPA has developed the FIPA Abstract Architecture Specification which specifies the standard architecture that heterogeneous agent platforms should comply with to be able to communicate each other.

According to the FIPA Abstract Architecture Specification (for more details see FIPA Specifications, Foundation for Intelligent Physical Agents, 2000, <http://www.fipa.org/repository/index.html>), a server agent should register its services with a directory facilitator (DF) and client agents should contact the DF to find an appropriate server agent that provides the required services. The client agent creates a service description that contains the service name, type, protocol, ontology, and content language to be used for the service and uses the service description to query the DF to find suitable server agents. However, this has the limitation that a client agent is only able to request services which are already known to it (for example, see Steven Wilmott, Jonathan Dale, Bernard Burg, Patricia Charton and Paul O'Brien, "Agentcities: A Worldwide Open Agent Network", Agentlink News, No. 8, Nov.

2001, available at <http://www.AgentLink.org/newsletter/8/AL-8.pdf>, for more details). Moreover, FIPA addresses the issue of providing a mechanism that allows interoperability between agents in a variety of heterogeneous platforms by using a standard message structure or content language, ontology, and interaction protocol

5 (these standards can also be used within the same platform). However, the standards do not specify how existing agents can handle messages with any combination of new content language, ontology, or interaction protocol even if they reside on the same platform.

- 10 Another issue in relation to interoperability is the conversation policy used for the multi-agent interaction. Conversation policies, also called interaction protocols, are predefined sequences of agent messages that guide and constrain agent communications for specific objectives. They are essential in complicated agent conversations that involve a lot of messages and many possible branches of logic and
- 15 have been the subject of research by several parties, for example, see the earlier reference by Mamandou as well as Ren'ee Elio and Afsaneh Haddadi, "On abstract task models and conversation policies", in Working Notes of the Workshop on Specifying and Implementing Conversation Policies, pages 89-98, Seattle, Washington, May 1999; M. Greaves, H. Holmback, and J. Bradshaw, "What is a
- 20 conversation policy? ", in Proc. *The Workshop on Specifying and Implementing Conversation Policies*, Seattle, Washington, May 1999, pp. 118-131; Scott A. Moore, "On conversation policies and the need for exceptions", in Working Notes of the Workshop on Specifying and Implementing Conversation Policies, Seattle, Washington, May 1999; and Jeremy Pitt and Abe Mamdani, "Communication
- 25 protocols in multi-agent systems", In Working Notes of the Workshop on Specifying and Implementing Conversation Policies, pages 39-48, Seattle, Washington, May 1999.

Without a conversational policy, individual agents in each communication step may

30 face difficulties in determining how to communicate with each other by choosing which message type to use, based on their own understanding and implementation of the ACL semantics. It therefore is generally advisable to use conversation policies in all non-trivial conversations.

One of the limitations of known MASs is that agents use only a set of known or standard conversation policies and cannot handle ad-hoc conversation policies without re-implementation. The need for ad-hoc conversation policies is clear in

5 information-centric agents in e-markets that are characterized by their focus on collecting, processing, analysing, and monitoring information.

Information agents can be defined as a class of autonomous agents that are closely related with information sources (for more details see K. Decker, A. Pannu, K. Sycara, and M. Williamson, "Designing behaviors for information agents", in Proc. 10. *The First International Conference on Autonomous Agents (AGENTS-97)*, Feb. 1997, pp. 404-412). For these reasons, conversations with information agents can be dependent on the nature of information sources. As information sources range from legacy systems to web sites, etc, it is not appropriate to assume that in future they 15. will be able to be supported by a few standard conversation policies. Even now, it has been proposed that existing conversation policies are not extensive enough to support all applications and systems (see, for example, the above reference by Moore) and new policies will need to be implemented and present policies upgraded in future. A conversation policy handshaking mechanism to allow agents to exchange

20. ad-hoc conversation policies and interact after interpretation of the new conversation policy on the fly is already known in the art from Hyung Jun Ahn, Habin Lee, Hongsoon Yim, Sung Joo Park, "Handshaking Mechanism for Conversation Policy Agreements in Dynamic Agent Environment," *First International Joint Conference on Autonomous Agents and Multi-Agent Systems (AAMAS 2002)*. However, this ad- 25. hoc interaction protocol is not able to handle messages with unknown language and ontology.

A service component concept for MAS has been adopted in the European 5th Framework project LEAP (Lightweight Extensible Agent Platform) (see LEAP Project 30. website, <http://leap.crm-paris.com>). In the LEAP project, a Generic Service Component (GSC) construct was designed, and 22 specializations of it, covering three application areas (that is, knowledge management, travel management, and decentralised work co-ordination management) were produced (a subset of which

were actually implemented) to be used in a wide variety of applications. However, whilst the main objective of a LEAP GSC is to provide generic service components which can be reused in similar applications, the GSC construct developed in the LEAP project is a static library that is used when agents are developed, and which must be

5 present when they are launched on an agent platform. Consequently, the generic service components proposed by LEAP cannot be dynamically installed on to agents which are already running.

In electronic commerce (eCommerce), MAS are considered to play a major role (see
10 for example, Maes, Pattie, Guttman, R. H., and Moukas, A. G. "Agents That Buy and Sell", Communication of the ACM, Vol. 42, No. 3, pp.81-91, 1999). In eCommerce, autonomous agents can act on behalf of their human users to buy or sell products or services and the openness and flexibility of the MAS will affect its success. The eCommerce environment is dynamic in that new consumers and merchants may
15 appear, new products and services can be introduced frequently, and sometimes the standard languages and transaction rules can be changed. As a result, any MAS implemented in an eCommerce environment needs to be flexible enough to adapt to frequent changes in eMarket settings. More specifically, a MAS for eCommerce should enable agents to participate, disengage, and/or transact with each other using
20 new business rules (subject to some minimum constraints) whenever these new rules arise.

In order for a known MAS to become sufficiently open and flexible for the eCommerce environment, all participating agents would be required to use the same
25 content languages, ontologies, and interaction protocols in the messages they exchange. This is unrealistic to achieve using known MASs as this prerequisite makes it impossible for agents providing new services based on a new interaction protocol, ontology, or content language to participate in any existing MAS-based markets. To accommodate such an agent, the MAS would have to be re-engineered to allow
30 existing agents to use the new content language, ontology, or interaction protocol to request and receive service from the new agent.

The present invention seeks to obviate and/or mitigate the above problems and disadvantages known in the art by providing a multi-agent system architecture which provides sufficiently flexibility to support an evolving eCommerce environment.

5 A first aspect of the invention seeks to provide a service component arranged in use to enable a client agent to interact with a server agent when requesting a service, the service component comprising: a plurality of role components arranged in use to perform a service interaction between the client agent and the server agent, the role components being loaded onto said client and server agents as appropriate for the
10 interaction and when loaded arranged to provide the client and server agents with information on the interaction requirements to enable the requested service to be provided.

Preferably, the initiator role components are provided by a service provider agent to a
15 service consumer agent.

Preferably, the role components are attached with a component description, the component description including details of the minimum client platform capability of the client agent and the interfaces used by the client agent to interact with the role
20 component.

Preferably, the initiator role component can control its state and can be reused for multiple requests.

Preferably, the role components are distributed by a mediator agent.

25 Preferably, the mediator agent provides the role components dynamically to the client and server agents.

More preferably, the mediator agent identifies a suitable role component using a
30 service description and component description of the role component.

Preferably, one of said plurality of role components is an Initiator role component provided dynamically to the client agent whilst the client agent is running.

Preferably, one of said plurality of role components is a Respondent role component provided dynamically to the server agent whilst the server agent is running.

- 5 A second aspect of the invention relates to a service component arranged to enable a client agent to interact with a server agent when requesting a service, the service component comprising: a plurality of role components arranged to perform a service interaction between the client agent and the server agent, the role components providing the client and server agents with information on the interaction requirements to enable the requested service to be provided, wherein the service component is generic to the client and server agents and is dynamically installed into
10 at least one of the client and server agents when these agents are already running.

- A third aspect of the invention relates to a multi-agent service architecture having a
15 service component arranged to enable a client agent to request a service from a service agent, the architecture including: a mediator agent arranged to provide a role component to the client agent, wherein once the role component is loaded on the client agent, the client agent is provided with information which enables the service to be provided by the service agent.

20

- A fourth aspect of the invention relates to a method of providing a user with access on demand to a remote service, the method comprising the steps of: generating a client agent for the user to request the service from a server agent; providing the client agent with at least one service component arranged to modify the client agent
25 to enable the client agent to interact with the server agent when requesting the service; forwarding the modified client agent to the broker to enable the server agent and modified client agent to interact; and responding to the client agent's request to provide the requested service, wherein the service component provided comprises: a plurality of role components arranged to perform service interactions between the
30 client agent and the server agent, the role components providing the client and server agents with information on the interaction requirements to enable the requested service to be provided.

A fifth aspect of the invention relates to a method of enabling a software agent to participate in an inter-agent interaction in a MAS architecture, the method comprising the steps of: determining at least one of a plurality of role components for use by a service component of said software agents required for participation in the inter-agent interaction; identifying a mediator agent in the MAS which is capable of providing at least one role component required by the software agent for participation in the inter-agent interaction, the mediator being identified by means of a service component description as having a suitable role component for the service component; dynamically installing the role component provided by the mediator agent on the software agent; and loading the role component on the software agent to enable the software agent to participate in the inter-agent interaction.

A sixth aspect of the invention relates to an agent internal architecture for dynamically installing and executing role components, the architecture comprising:

- 15 a Co-ordinator controller, a Load manager, a Component installer, and a Package manager.

A seventh aspect of the invention relates to a method of enabling a software agent to manage downloaded role components, the method comprising the steps of:

- 20 determining whether there are any components downloaded already in local component storage; performing version checking for downloaded initiator components if there exist any initiator components; locating the Mediator agent and downloading any initiator components from the Mediator Agent; packaging the downloaded initiator components into local component storage; and instantiating the
- 25 downloaded initiator components.

An eighth aspect of the invention relates to a computer product comprising a suite of one or more computer programs provided on a computer readable data carrier, the one or more computer programs being arranged to implement any one of the method

- 30 aspects of the invention.

A ninth aspect of the invention relates to a signal conveying a suite of one or more computer programs over a communications network, the suite of one or more

computer programs be arranged when executable to implement any one of the method aspects of the invention.

It will be appreciated by those skilled in the art that the invention can be implemented

5 in any appropriate combination of software and hardware, and that invention can also be implemented by a synergy of software and hardware, for example, when a computer software product comprising one or more computer programs arranged to implement any one of the method aspects of the invention is run on a computer.

10 Advantageously, the architecture of the invention enables agents residing on the same agent platform to interact using a new language, ontology, or interaction protocol. Advantageously, an ad-hoc interaction protocol is provided by the architecture which can handle messages with unknown language and ontology.

15 Advantageously, the generic service components of the invention can be dynamically installed into agents which are already running.

The features of the invention as defined above or by the dependent claims may be combined in any appropriate manner with any appropriate aspects of the invention

20 as apparent to those skilled in the art.

The preferred embodiments of the invention will now be described with reference to the accompanying drawings, which are by way of example only and in which:

25 Figure 1 shows the internal architecture of a conversational service component according to the invention;

Figure 2 shows the internal structure of a role component of the conversational service component of Figure 1;

Figure 3A shows a state transition diagram of an initiator role component according
30 to the invention;

Figure 3B shows a state transition diagram of a respondent role component according to the invention;

Figure 4 shows generic agent roles in a multi-agent architecture according to the invention;

Figure 5 shows the structure of the co-ordination engine and the process for downloading, installation, and execution of an initiator component according to the

5 invention;

Figure 6 shows the process for loading an instance of a conversational service component according to the invention; and

Figure 7 shows an embodiment of the invention where a user is requesting services on demand from a server.

10

There follows a detailed description of the preferred embodiments of the invention, which include a description of the best mode of the invention as currently contemplated by the inventors. Even where not explicitly described, it will be apparent to those skilled in the art that certain features of the invention can be replace by their known equivalents, and the scope of the invention is intended to encompass such equivalents where appropriate.

15

Overview

One embodiment of the invention provides a multi-agent system (MAS) architecture

20 which allows plug-and-play of service components (C-COMs) into software agents to facilitate inter-agent interactions. The C-COM provides a "conversational" facilitator for the inter-agent interaction. The C-COM software is arranged to enable required agent interactions (i.e. a request and response) to occur for a given service when loaded appropriately onto the agents participating in the interaction. The C-COM

25 structurally comprises a plurality of role components for the interaction (where the number of role components provided is determined by the number of roles needed for the interactions). All the service interactions are performed via messages which can be interpreted and composed by the role components. As the role components are aware of the content language, ontology, and interaction protocol used for a given

30 service, an agent can participate (as a client, a server or both) just by installing one or more C-COMs for a given service, even if the agent has no awareness of the required content language or interaction protocol.

The generic roles for the C-COMs are 'Initiator' and 'Respondent'. These roles can be specialized into more roles according to the application requirements. The 'Initiator' role component is installed in a client agent and is required to obtain the service result from a server agent. The 'Respondent' role component is installed in a server

5 agent in order to provide services to other client agents. The client agent and server agents interact via the messages which are generated and interpreted by their respective role components according to a pre-defined content language, ontology, and interaction protocol for the service in question.

10 One embodiment of the invention provides a mediator agent for a multi-agent architecture (MAS) which provides the role components to the software agents dynamically, i.e., on the fly. For example, a mediator agent may provide an 'Initiator' role component to a client agent dynamically whilst the client agent is already running in the MAS. As a result, the client agent does not need the 'Initiator' role
15 component a priori, instead, the client agent can request a service and receive it without prior knowledge of the content language or interaction protocol required by the server providing the requested service.

The appropriate mediator agent for a software agent in a MAS is identified by means

20 of whether it has a suitable initiator role component for the software agent's desired inter-agent interaction. This is achieved through the use of a service component description of the service component which contains a plurality of role components, including the necessary Initiator and Respondent role components. The mediator agent then provides the role components dynamically and these are loaded on the
25 software agent whilst the agent is running in the MAS. Once an initiator role component is loaded from a mediator agent, the client agent is directly able to request a service from the available service agent. Suitable server agents are identified by the downloaded initiator role component when the client agent executes it to get a service result.

30 Advantageously, the resulting MAS has a very loosely coupled architecture which allows agents to join, disengage and/or rejoin with minimal impact, just by installing one or more C-COMs.

A service component (C-COM) for plug and play in a software agent in a multi-agent system (MAS) is therefore a software component which is used as the principle means of interaction between software agents, and which can, in preferred embodiments of the invention, be installed and executed by a software agent dynamically.

C-COM architecture

Referring now to Figure 1, the structure of a service component (C-COM) for a software agent according to a first embodiment of the invention is shown schematically. In Figure 1, C-COM 1 comprises four role components 2,3,4,5. Each role component 2, 3,4, 5 can be plugged dynamically into an agent. Four schematic agents are shown in Figure 1, agents 6, 7, 8, 9.

From an agent's point of view, each role component is a black box which hides the interaction protocol 10 with other role components and just shows an interface which specifies the input and output data needed to execute the role component. As shown in Figure 1, a role component 2,3,4,5 is plugged into an agent 6,7,8,9 respectively when that agent 6,7,8,9 participates in an interaction. However, more than one role component can be plugged into an agent. An agent which installs a role component is called a Master Agent of the role component.

The C-COM is an implementation of an interaction pattern which is a template of a frequently used interaction scenario amongst roles (for example, the interaction pattern for an auction can be described as follows: First, the seller advertise something to sell, second, the buyers send their bids to the seller, finally, the seller sells the product to a buyer who has sent the best bid before the closure of the auction). The C-COM is formed as a re-usable software component based on this interaction pattern and is generated in a form which can be dynamically installed on and executed by other software agents.

According to this embodiment of the invention, the conversational component (C-COM) is therefore defined as an implementation of a reusable interaction pattern which produces a service via interactions among role components within the

conversational component. The interactions between role components of the C-COM are controlled by an Interaction Protocol. Each role component performs actions in each stage of the Interaction Protocol to produce the required service.

Accordingly, the CCOM can be denoted as follows:

$$5 \quad ccom = \langle ip, Cs \rangle$$

where ip is an Interaction Protocol, as defined below, and

Cs is a set of finite state machine-like components having one or more roles defined in ip .

- 10 The term Interaction Protocol (ip) describes what sequences of which messages are permissible among a given set of roles, for example, see the specifications of standard interaction protocols (by FIPA) from <http://www.fipa.org/repository/ips.html>.

- A role component is defined as a finite-state-machine that performs actions according to its current state to produce the required service. A role component reveals a set of interfaces to its user.
- 15

Referring now to Figure 2, an internal structure of a role component is shown schematically. Each role component consists of four main modules: a Protocol

- 20 Manager 11, an Interface (either an Inner interface 12a or an outer interface 12b although both are shown in Fig. 2), an Action 13, and Message Handler 14.

- The Protocol Manager 11 controls all the actions of a role component according to the interaction protocol employed by the role component and the nature of the role component in the interaction protocol (see Figure 1). The Protocol Manager 11 interacts with the Message Handler 14 to send and receive messages. The Message Handler 14 filters messages which are sent to the role component from the message queue of its Master Agent.
- 25

- 30 In the context of the invention, both interfaces 12a, 12b are defined as a set of method signatures that specify the method name, input arguments, and output of the method (c.f. the definition of 'Interface' in Java). When a role component interacts

with its Master Agent, the Master Agent installs the implementation of the appropriate interface 12a or 12b, in accordance with the role of role component 2.

5 Inner interface 12a defines a trigger method (in that a call to the method by a service consumer activates the function of the whole C-COM) which is called by a service consumer to get a service result from the role component 2. The role component 2 implements the inner interface 11a to produce the required service result.

10 Outer interface 12b defines methods which are called by the role component 2 to get application specific input. The agent which installs the role component 2 should provide an implementation of the outer interface 12b. Then, the role component 2 interacts with the implementation to produce the required service result.

15 An Initiator component is a role component which has an inner interface 12a, but not an outer interface 12b. A Respondent component is a role component which has an outer interface 12b, but not an inner interface 12a. The Initiator component is activated when the trigger method defined by the inner interface 12a is called by a service consumer. The activated Initiator component initiates interactions with Respondent components within a C-COM to produce a service result. Details of the
20 state transitions of an Initiator role component are shown in Figure 3A and discussed in more detail herein below.

The Respondent component is activated when a triggering message arrives from an Initiator component. Detail of the state transitions of a Respondent role component
25 are shown in Figure 3B and discussed in more detail herein below.

In this context, a triggering message is defined as the first message for the role the Respondent component is responsible for, in the Interaction Protocol 10 employed in the C-COM.

30

The outer interface 12b enables the customisation of the role component 2 for different application requirements. For instance, a Respondent component can be

reused in different applications by providing different implementation of outer interface 12b.

Figure 2 also shows state transitions within a role component. When a role component is installed into a Master Agent, the component has "Ready" state. When any methods in Inner Interface/Outer Interface or Actions are executed by Protocol Manager 11, the component transit to next states ("State 2", "State 3", and finally "Completed"). Once the component reaches to "Completed" state, it automatically resets its state to "Ready" waiting another request from a service consumer (for the Initiator role component) or the Initiator role component (for the Respondent role component).

The Initiator and Respondent components are generic in that they can be specialised for more specific role components according to the requirements of the target C-COM. A Master Agent can handle multiple trigger messages concurrently by installing multiple Respondent components. Figures 3A and 3B show the state transition diagrams which show the internal functionality of the Initiator and Respondent components respectively.

In Figure 3A, an installed component is initially in an "Idle" state 20. After a service request has been issued, the component is in the "Schedule Next Behaviour" state 21. The behaviour execution request then causes the component to execute the behaviour (state 22) and once this is finished the component returns to its schedule next behaviour state 21. When a new interaction is required the component prepares request message 23. Once the request message has been sent, the component is in a wait response message state 24. Once the response message has been received, the component is in a handle response message state 35. The response message is then interpreted by the software component which then enters its "Schedule Next Behaviour" state 21, before delivering the service result and returning to the idle state 20.

30

In Figure 3B, an installed component is initially in the "Idle" state 26. After a service request has been issued, the component is in the "Schedule Next Behaviour" state 27. The behaviour execution request then causes the component to execute the

behaviour (state 28) and once this is finished the component returns to the "Schedule Next Behaviour" state 27. When a new interaction is required the component enters the "Activate Agent Interface" state 29. Once the agent response is received, the component again returns to the "Schedule Next Behaviour" state 27. The response message is then prepared and the agent enters the "Send Response Message" state 30. Once the message has been sent, the agent returns to the "Schedule Next Behaviour" state 27 before returning to "Idle" state 26.

Another embodiment of the invention relates to a multi-agent architecture (CCoMaa) in which agents are able to interact with each other through C-COM. This allows existing agents to interact with new service-providing agents by dynamically installing and executing Initiator components which are provided by the new service providing agents. To facilitate this dynamic configuration change management, the CCoMaa needs special agents having predefined roles. Fig. 4 shows schematically some generic agent roles in the CCoMaa and their interactions.

In the multi-agent architecture (MAS) according to the invention, an agent may have one of a plurality of roles. For example, as Fig. 4 shows schematically, the agent may be a service provider agent (SPA) 41, a service mediator agent 42, and a service consumer agent (SCA) 43. It will be appreciated by those skilled in the art that the term "SPA" is equivalent in use to the term "server agent" and that the term "SCA" is equivalent to "client agent".

The SPA 41 registers the service description, component descriptions, and executable Initiator components (actions "A" shown in Fig. 4). The SPA 41 registers its service description to the service mediator agent 42 by a process which differs from the one defined by FIPA.

More specifically, the SPA 41 registers an executable Initiator component, a component description (which is used by the SCA for installation and execution of the executable Initiator component), and a service description. Advantageously, as the Initiator component generates and interprets all messages which will be exchanged by the SPA 41 with a SCA 43, there is no need for a SCA 43 to have

knowledge a priori to requesting a service of the requirements imposed by the SPA 41.

The service mediator agent 42 is responsible for maintaining the service registry and

5 Initiator library that contains Initiator components (actions "B" in Fig. 4). The service registry plays the role as defined in FIPA specifications or other similar systems. The Initiator library maintains the pair of component description and the executable Initiator component. The component description specifies the information needed to install and execute the executable Initiator component.

10

The difference between the service registration process in this invention and that of FIPA can be explained in detail as follows. In the FIPA specifications, a FIPA SPA registers its description to a Directory Facilitator (DF) agent as per the following example;

15

```
<DFAgentDescription>
```

```
  <Name>
```

```
    <Agent-Identifier name="routeplanner@foo.com",  
address="iiop://foo.com/acc" />
```

20

```
  </Name>
```

```
  <Protocol name="AdHoc-Protocol" />
```

```
  <Ontology name="Travel" />
```

```
  <Language name="FIPA-SLO" />
```

```
  <Language name="KIF" />
```

25

```
  <ServiceDescription>
```

```
    <Name>bookFlight </Name>
```

```
    <Type> BookingService </Type>
```

```
    <Ontology> Travel </Ontology>
```

```
    <Protocol> FIPA-Request </Protocol>
```

30

```
    <Property name=domain, value=international />
```

```
  </ServiceDescription>
```

```
</DFAgentDescription>
```

The DF agent stores the DF agent description in its local table. When a SCA sends a request message to the DF agent to find a SPA for a given service, the DF agent returns the names of any suitable SPAs it finds to the SCA. Once the SCA receives the name of one or more SPAs, it starts an interaction with those SPAs employing the ontology, language, and interaction protocol specified in the service description.

The format of the query message the SCA sends to the DF agent is as follows:

```
(request
  :sender (agent-identifier :name SCA@foo.com :address iiop://foo.com/acc)
10  :receiver (agent-identifier :name Mediator@foo.com :address
  iiop://foo.com/md)
  :language FIPA-SLO
  :protocol FIPA-Request
  :ontology CCOM-Management
15  :content
    (action (agent-identifier :name Mediator@foo.com :address
    iiop://foo.com/md)
    (search
      (ccom-agent-description
20      :ontology (set Travel)
      :language (set FIPA-SLO KIF)
      :services (set
        (service-description
          :name bookFlight
25          :type BookingService
          :ontology Travel
          :language SLO
          :protocol FIPA-Request
          :properties (set
30          (property :name domain :value
international)))))))))
```

The above message is used by the Mediator Agent to find appropriate SPAs and returns the list of names of suitable SPAs (with each entry in the form of "<Agent-Identifier name="routeplanner@foo.com", address="iiop://foo.com/acc" /> ") to the SCA.

5

On the other hand, the SPA in this invention registers the following form of description to a Mediator agent:

```

10  <CCOMAgentDescription>
    <Name>
        <Agent-Identifier
            name="dummy@foo.com",
            address="iiop://foo.com/acc"/>
        </Name>
        <Protocol name="AdHoc-Protocol" />
15  <Ontology name="Travel" />
    <Language name="FIPA-SLO" />
    <Language name="KIF" />
    <ServiceDescription>
        <Name> bookFlight </Name>
20  <Type> BookingService </Type>
    <Ontology> Travel </Ontology>
    <Property name=domain, value=international/>
    </ServiceDescription>
    <ComponentDescription>
25  <package name="com.travelagent.booking"
        mainclass="Flight_initiation.class" />
    <MinJVM> JDK1.1.x </MinJVM>
    <InnerInterface>
        <Method name=getTicket>
30  <Input
            order=1,
            name="Route",
            type=Travel.Booking.Route />
        <Output type=Travel.Booking.TicketList />
    </Method>

```

```

    </InnerInterface>
  </ComponentDescription>
</CCOMAgentDescription>

```

- 5 Once the service provider has registered its service(s), any SCA 43 can contact the service mediator agent 42 to get contact information for the SPAs 41. To get the contact information, the SCA 43 sends a message that contains a service description to the service mediator agent 42 (action "C" in Fig. 4). The content of the message can be as the following example.

10

```
(request
```

```
  :sender (agent-identifier :name SCA@foo.com :address iiop://foo.com/acc)
  :receiver (agent-identifier :name Mediator@foo.com :address
```

```
  iiop://foo.com/md)
```

15

```
  :ontology CCOM-Management
```

```
  :language SLO
```

```
  :protocol FIPA-Request
```

```
  :content
```

```
    (action (agent-identifier :name Mediator@foo.com :address
```

```
    20 iiop://foo.com/md)
```

```
      (search
```

```
        (ccom-agent-description
```

```
          :services (set
```

```
            (service-description
```

25

```
              :name bookFlight
```

```
              :type BookingService
```

```
              :properties (set
```

```
                (property :name domain :value
```

```
                international))))
```

30

```
          :component (set
```

```
            (component-description
```

```
              :min-jvm jdk1.2.x
```

```

:inner-interface (set (method :input
Travel.Booking.Route))))))

```

This request message is also different from that of FIPA. Note that the SCA doesn't

- 5 have to specify language and protocol in a service description used for service acquisition. The service mediator agent 42 then tries to match the service description and component description with one provided by SPA 41. If a matching agent description is found, the mediator agent 42 returns the agent description of the SPA 41 and an executable Initiator component to the SCA 43 (actions "D" in Fig. 4). If
10 any contact information is returned by the service mediator agent 42, the SCA 41 installs the executable Initiator component into its Initiator library, based on the component description (action "E") and executes the Initiator component to get the service result from the SPA (actions "F" and "G").

15 Dynamic download, installation and execution of C-COM

The SCA 41 shown in Fig. 4 is equipped with a co-ordination engine which is responsible for downloading, installing, and executing an Initiator component.

Referring now to Figure 5, the structure of the co-ordination engine and the process

- 20 for downloading, installation, and execution of an Initiator component is shown schematically.

- In Figure 5, a co-ordination controller 51 activates a load manager module 52 when an executable Initiator component instance is requested to perform a required service
25 by another component from the SCA 43 (see Fig. 4). If the Initiator component has already been downloaded before, the load manager 52 module may (depending upon the requirements of the application) perform a version check to ensure that the latest version is installed. The versioning process is determined by the version control scheme currently in place. Otherwise the load manager 52 module will instantiate the
30 Initiator component and pass the instantiated object back to the co-ordination controller 51 where it will be executed. If there is no locally installed copy of the Initiator component the load manager module 52 forwards a request to the

component installer module 53, which will attempt to locate a service mediator agent 42 (see Fig. 4) that contains the required Initiator component.

There are a variety of mechanisms that can be used to discover the available service mediator agents within the network. For example, if the application is running on a FIPA compliant agent platform, the directory facilitator can be used. When the component installer module 53 locates a C-COM that matches the given requirements, the component installer 53 downloads the Initiator component of the C-COM.

The component installer 53 then returns the results of its search to the load manager 51. If successful the request will contain the initiator portion of the Initiator component. The load manager 51, then, stores a copy of the Initiator component within the C-COM library 55, and requests that the Package manager 54 installs the Initiator component so that it can be executed. The Package manager 54 then loads the files into the file system, and control will return to the load manager 51. Once the Initiator has been downloaded and stored, the load manager 51 records the details of the process so that in future the Initiator component does not need to be downloaded again unless a new version becomes available. The result of the interaction with the SPA 41 is returned to the requester of the service result.

Fig. 6 shows steps in a method for loading an instance of a C-COM by the collaboration of Load Manager 52, Component Installer 53, and Package Manager 54 in Figure 5. First, Load Manager 52 asks Package Manager 54 if there are any initiator-role components available for a service request. If there exists any initiator-role components 61, then the Load Manager 52 performs a version check 63 by sending a command to the Component Installer 53. The Component Installer 53 contacts the Mediator Agent 42 to get the latest version number for the corresponding initiator role components. If the local initiator role component is the latest version, the Load Manager 52 instantiate the role component and returns the instance to the Coordination Controller 51 and finishes the process 69.

If there is no role component managed by the Package Manager 54, the Load Manager 52 asks the Component Installer 53 to download any initiator component. Then the Component Installer 53, first, locates a Mediator Agent 62. If no Mediator Agent is found 65, the process is finished. Otherwise, the Component Installer 53

5 queries the found Mediator Agent 42 to get any appropriate initiator components 64. If found, the Component Installer 53 downloads the found initiator components 66 and passes them to the Package Manager 54 to store in its local component store for later use 68, and finally instantiates the initiator component 67 and finishes the process 69.

10

Advantageously, one embodiment of the invention can be used to implement a dynamic version management system in which service providers can upgrade services without affecting their customers by providing upgraded initiator components on the mediator agent. The SCA needs to only compare versions of the
15 local initiator and remote initiator when it contacts the mediator agent. The version upgrade is then done automatically before actual interaction with the SPA is performed by the SCA, in a manner which is hidden from any human users.

Another embodiment of the invention enables a user to have improved access on-

20 demand to the latest version of an application provided by a remote service over a data communications network. For example, referring now to Fig. 7 of the accompanying drawings, a schematic diagram is indicating how a first user 70 can be provided with access on-demand to remote services provided by service provider 71 via a brokerage 72. The application used by user 70 provides a client agent which
25 interfaces with an initiator component 73 provided by a suitable mediator agent provided by brokerage 72. Initiator component 73 then interacts with a respondent component 74 set up by the mediator agent, and is then able to interface with a SPA of the service provider 71. The initiator and respondent roles form part of a C-COM arranged to facilitate the software agents' interaction with
30 each other in the manner described hereinabove with reference to the other embodiments of the invention. The first user 70 is able to access the latest version of the service they have requested from the service provider without having any previous requirement to install any components specific to that version, as any

required conversational components (i.e. initiator and responder) will be installed as appropriate dynamically into the brokerage agent. Moreover, once the client agent of a second user 75 is provided with access to an appropriate initiator component 76, the client agent is able to interact directly with respondent component 74 as this is

5 already associated with that type of Initiator role component.

In this way, the service provider and user agents can interact regardless of previous awareness of the interaction protocol or language required by the particular version of the application which the user wishes to access.

10 Advantageously, another embodiment of the invention can be used to implement a web service portal where new web service providers can be registered without affecting other existing agents.

15 It will be appreciated by those skilled in the art that many aspects of the invention can be implemented in either software and/or hardware and that the spirit of the invention is intended to cover embodiments in any combination of software and/or hardware as appropriate, and that software elements of the invention can be provided by a computer product which may comprise a signal communicated over a

20 communications network, for example, as a downloadable suite of one or more computer programs, and/or as a suite of one or more computer programs provided on a computer readable data carrier, which are able to execute the invention when loaded and run on an appropriate device.

25

CLAIMS

1. A service component arranged in use to enable a client agent to interact with a server agent when requesting a service, the service component comprising:

5 a plurality of role components arranged in use to perform a service interaction between the client agent and the server agent, the role components being loaded onto said client and server agents as appropriate for the interaction and when loaded arranged to provide the client and server agents with information on the interaction requirements to enable the requested service to be provided.

10 2. A service component as claimed in claim 1, wherein the initiator role components are provided by a service provider agent to a service consumer agent.

3. A service component as claimed in either claim 1 or claim 2, wherein the role
15 components are attached with a component description, the component description including details of the minimum client platform capability of the client agent and the interfaces used by the client agent to interact with the role component.

4. A service component as claimed in any previous claim, wherein the initiator role
20 component can control its state and can be reused for multiple requests.

5. A service component as claimed in any preceding claim, wherein the role components are distributed by a mediator agent.

25 6. A service component as claimed in claim 5, wherein the mediator agent provides the role components dynamically to the client and server agents.

7. A service component as claimed in any one of claims 5 or 6, wherein the mediator
30 agent identifies a suitable role component using a service description and component description of the role component.

8. A service component as claimed in any preceding claim, wherein one of said plurality of role components is an Initiator role component provided dynamically to the client agent whilst the client agent is running.

5 9. A service component as claimed in any preceding claim, wherein one of said plurality of role components is a Respondent role component provided dynamically to the server agent whilst the server agent is running.

10 10. A service component arranged to enable a client agent to interact with a server agent when requesting a service, the service component comprising:

a plurality of role components arranged to perform a service interaction between the client agent and the server agent, the role components providing the client and server agents with information on the interaction requirements to enable the requested service to be provided, wherein the service component is generic to the client and server agents and is dynamically installed into at least one of the client and server agents when these agents are already running.

15 11. A multi-agent service architecture having a service component arranged to enable a client agent to request a service from a service agent, the architecture including:

a mediator agent arranged to provide a role component to the client agent, wherein once the role component is loaded on the client agent, the client agent is provided with information which enables the service to be provided by the service agent.

25 12. An agent internal architecture for dynamically installing and executing role components, the architecture comprising:

a Co-ordinator controller;

a Load manager;

30 a Component installer; and

a Package manager.

13. A method of providing a user with access on demand to a remote service, the method comprising the steps of:

generating a client agent for the user to request the service from a server agent;

5 providing the client agent with at least one service component arranged to modify the client agent to enable the client agent to interact with the server agent when requesting the service;

forwarding the modified client agent to the broker to enable the server agent and modified client agent to interact; and

10 responding to the client agent's request to provide the requested service, wherein the service component provided comprises:

a plurality of role components arranged to perform service interactions between the client agent and the server agent, the role components providing the client and server agents with information on the interaction requirements to enable
15 the requested service to be provided.

14. A method of providing a user with access on demand to a remote service as claimed in claim 13, wherein the plurality of role components are provided by a mediator agent.

20

15. A method of enabling a software agent to participate in an inter-agent interaction in a MAS architecture, the method comprising the steps of:

determining at least one of a plurality of role components for use by a service component of said software agents required for participation in the inter-agent
25 interaction;

identifying a mediator agent in the MAS which is capable of providing at least one role component required by the software agent for participation in the inter-agent interaction, the mediator being identified by means of a service component description as having a suitable role component for the service component;

30 dynamically installing the role component provided by the mediator agent on the software agent; and

loading the role component on the software agent to enable the software agent to participate in the inter-agent interaction.

16. A method as claimed in claim 15, wherein the software agent is a client agent, and the role component is an initiator role component, and the inter-agent interaction comprises a request for a service by the client agent from a server agent.

5

17. A method of enabling a software agent to manage downloaded role components, the method comprising the steps of:

determining whether there are any components downloaded already in local component storage;

10

performing version checking for downloaded initiator components if there exist any initiator components;

locating the Mediator agent and downloading any initiator components from the Mediator Agent;

15

packaging the downloaded initiator components into local component storage; and

instantiating the downloaded initiator components.

18. A computer product comprising a suite of one or more computer programs provided on a computer readable data carrier, the one or more computer programs

20

being arranged to implement any one of the methods of claims 13 to 17.

19. A signal conveying a suite of one or more computer programs over a communications network, the suite of one or more computer programs be arranged when executable to implement any one of the methods of claims 13 to 17.

ABSTRACT

A service component enables client/server interactions even when information on the content language and/or interaction protocol required for the service the client agent has requested from the service agent is not known *a priori*. The service component has a generic structure comprising a plurality of role components which perform the service interaction between the client agent and the server agent and which provide sufficient information on the interaction requirements to enable the requested service to be provided.
